Genetic evaluation systems

- ❖ Breeder submits phenotypes and pedigree
- ❖ Genetic evaluation system returns BLUP EBVs
 - plus other useful information e.g. selection indexes, accuracies, inbreeding coefficients
- ❖ Can be
 - Within herds
 - Across herds, within breeds
 - Across herds, across breeds (best)

Properties of BLUP EBVs

Properties of BLUP EBVs

On Understanding LAMBPLAN EBV's

How to read a LAMBPLAN report:

Note: A useful rule of thumb for converting ram EBVs into lamb production is to simply halve the EBV (as rams contribute half the genetics of the lamb)

As before a guide to the relative importance of each trait is provided by the EBV's. The larger the EBV, the more important the trait is to the particular stud.

1 Lamb	Tag Lamb	Stead	1000	Tag Lamb (Health Score)	1000
0.000	0.5	0.5	0.5	0.5	0.5

Tag Lamb: This is the most important trait of a lamb and the most important trait of a stud.

Stead: This is the most important trait of a stud.

1000: This is the most important trait of a stud.

Tag Lamb (Health Score): This is the most important trait of a stud.

1000: This is the most important trait of a stud.

MLA's LAMBPLAN database records one million sheep

Milly, a White Suffolk lamb is the one millionth animal to have been objectively measured and recorded on Meat and Livestock Australia's LAMBPLAN terminal sire database.

MLA LAMBPLAN manager Dr Alex Ball said this was a great achievement for the national genetic evaluation program LAMBPLAN and the genetic improvement of the Australian prime lamb industry.

"Recording the one millionth sheep in the LAMBPLAN terminal sire database reinforces the integrity of the system and what it has to offer," Dr Ball said.

"Since 1989, when LAMBPLAN first started operating, the Australian prime lamb industry has seen some phenomenal improvements in live weight growth, increased eye muscle area and decreases in fat.

"In fact genetic improvements have seen post weaning weights of 6-8 month lambs increase by 5.8 kilograms, fat decrease by 0.4mm and eye muscle area improve by 0.3mm."

For the average lamb producer this means an extra \$5.80 per lamb produced in carcase value alone.

Australian Sheep Genetics Database

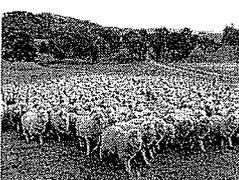

Australian wool and sheepmeat producers will have a tool to unlock higher levels of economic gain in their flocks thanks to the Australian Sheep Genetics Database (ASGD), a joint initiative of Australian Wool Innovation Limited (AWI), Meat & Livestock Australia (MLA).

The ASGD is designed to create a national database of genetic information for sheep producers to improve selection and breeding decisions. The ASGD will provide a national database of genetic information and selection decisions for sheep producers to improve selection and breeding decisions.

The ASGD will be a national database of genetic information for sheep producers to improve selection and breeding decisions. The ASGD will be a national database of genetic information for sheep producers to improve selection and breeding decisions.

The ASGD will be a national database of genetic information for sheep producers to improve selection and breeding decisions. The ASGD will be a national database of genetic information for sheep producers to improve selection and breeding decisions.

The ASGD will be a national database of genetic information for sheep producers to improve selection and breeding decisions. The ASGD will be a national database of genetic information for sheep producers to improve selection and breeding decisions.

Currently within the industry there are three main national genetic databases:

- Merino Benchmark database
- Merino Genetic Services database
- Central Test Sire Evaluation database (AMSEA)

There are also other smaller datasets sitting with CSIRO Select, Advanced Breeding Services and with private operators.

The ASGD will combine the three national Merino databases, as well as the other smaller industry databases.

The ASGD will produce one consistent, high quality set of breeding information in the form of quality assured Australian Sheep Breeding Values (ASBVs).

IAEA regional training course on selective breeding & gene technologies

BREEDPLAN INTERNATIONAL

BREEDPLAN is a modern genetic evaluation system for beef cattle breeders. It is based in Australia, with clients worldwide. BREEDPLAN offers bull breeders the potential to accelerate genetic progress in their herds, and to provide objective information on stock they sell to commercial breeders.

BREEDPLAN calculates Estimated Breeding Values (EBVs)* for a range of traits including:

Weight	Fertility	Carcass
Birth weight	Scrotal Size	Carcass weight
200-day milk	Days to Calving	Eye Muscle area
200, 400 and 600-day weight	Gestation length	Fat thickness
Mature cow weight	Calving ease	Meat Yield %
		Marbling

*(Note: EPDs are calculated for North American clients)

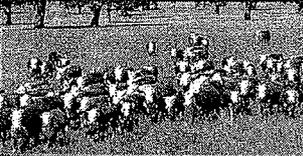

Included in the calculation of EBVs are the animal's own performance, the performance of known relatives, the heritability of each trait and the relationship between the different traits i.e. a world class genetic evaluation model, combining all traits in one analysis.

Properties of BLUP EBVs

Issue 14, January 2004

- Herford BREEDPLAN in America - page 3 & 4
- Fertility EBVs - page 6 & 7
- Brahman web use - page 9
- Multibreed maternal traits - page 10
- CRIC research - page 11
- Benchmarking - page 19

The top thing Herford breeders to be told is that they should not be afraid to try new things. The more genetic variation the better. This is a good program. Some of the things that are being done are: 1. More genetic variation in the herd. 2. More genetic variation in the sire. 3. More genetic variation in the dam. 4. More genetic variation in the offspring. 5. More genetic variation in the grand-offspring. 6. More genetic variation in the great-grand-offspring. 7. More genetic variation in the great-great-grand-offspring. 8. More genetic variation in the great-great-great-grand-offspring. 9. More genetic variation in the great-great-great-great-grand-offspring. 10. More genetic variation in the great-great-great-great-great-grand-offspring.

Towards global Herford genetic evaluation

The catalyst for the global evaluation will be the International Herford Genetic Exchange program. This is a global program between the USA, Australia, Brazil, Canada, France, Germany, Italy, Japan, Korea, Mexico, New Zealand, Norway, Sweden, Switzerland, Taiwan, Thailand, UK, USA, and Vietnam. The results of the linkage project and the development of global evaluation systems will be reported to the conference during a keynote session moderated by Dr. Hans Graw. David Johnston and Edna Douglas from the Animal Genetics and Breeding Unit (AGBU) - the genetic Research and Development group in Australia which develops the International BREEDPLAN genetic evaluation program.

The linkage project has been established using reciprocal matings of 12 commercial lines from Australia, the US and New Zealand across Australia, United States and Canada, with reciprocal links in the UK and Ireland. Property from the SA, USA are being fully evaluated for growth, live weight and carcass traits, with sample groups on display at the conference. The Australian property have links and working relationships with the USA.

Given that the performance data from Herford cattle in Australia and New Zealand is excellent in a BREEDPLAN evaluation and that strong genetic lines exist within the Herford population in both North and South America, global linkage will be established by the project.

The progress of moving to a global evaluation has been simplified because of the major Herford populations around the world will be using BREEDPLAN technology. A further bonus of the project will be the inclusion of EBVs in the herd. The simplification results already in form the linkage program demonstrate the accuracy of the EBVs in predicting property performance for these traits.

Bob Fries
Project manager and consultant to Australian Herford and Poll Hereford breeders

Properties of BLUP EBVs

PIGBLUP

What is PIGBLUP?

PIGBLUP is a PC based genetic evaluation system for pigs which has the potential to accelerate the genetic progress of herds thereby increasing their profitability.

It has been developed by the Animal Genetics and Breeding Unit (AGBU) since 1998 with funding from the Pig Research and Development Corporation and is marketed by ABRI.

PIGBLUP is based on BLUP models (Best Linear Unbiased Prediction), the most commonly used statistical method of assessing the breeding value of animals. The program was developed specifically for use in the pig industry, hence the name PIGBLUP. Breeders don't need to understand the statistical and genetic theory in order to use PIGBLUP.

Features of PIGBLUP

PIGBLUP has been designed to help breeders make the best selection decisions and to control their breeding program better. The program includes the following features:

- Calculation of Estimated Breeding Values (EBVs)
- An Economic Index of EBVs
- Graphical Display of Genetic and Environmental Trends
- Genetic Audit
- Mating Selection
- Data Screening
- Pig Kinship Workshop - November 1998

How effective is PIGBLUP?

A study of how well PIGBLUP predicts differences in performance between animals.

Compatible Herd Recording Systems

Accurate data recording and the correct data format is essential for running PIGBLUP. The following herd recording systems are compatible with PIGBLUP:

- Epiplanis
- Misa
- Resistor
- Hermap

For further information, contact:

The Agricultural Business Research Institute (ABRI)
The University of New England, Armidale, NSW 2351, Australia

Properties of BLUP EBVs

Consider the features we want in an EBV

Case study:

A breeder selects a young ram that has a high EBV based on his own phenotype only. The ram has 30 progeny and his EBV drops.

Why?

Properties of BLUP EBVs

Consider the features we want in an EBV

Case study:

A breeder is performing assortative mating. He sells his sire with the highest EBV - this sire produces in another herd and his EBV drops.

Why?

Properties of BLUP EBVs

Features of EBVs

High accuracy, for high response 'best'

- ❖ highest correlation between true and estimated breeding value

Lack of any bias, for fair comparison
'unbiased'

- ❖ true breeding values are distributed around predicted breeding values

Properties of BLUP EBVs

BLUP and accuracy

BLUP maximises EBV accuracy by

- ❖ calculating EBVs using all information sources
 - Information from relatives
 - Information from correlated traits
- ❖ using proper index weights
- ❖ just the same as a selection index
(note *BLP* = selection index)

Properties of BLUP EBVs

BLUP and lack of bias

BLUP ensures EBVs are unbiased

- ❖ unbiased EBVs are a matter of fair comparison
- ❖ note selection index (*BLP*) + *unbias* = *BLUP*

Properties of BLUP EBVs

What 'fixed effects' would need to be accounted for so all animals have comparable EBVs?

Date
of
birth

Herd A

Herd B

Properties of BLUP EBVs

The diagram illustrates two herds, Herd A and Herd B, with a vertical arrow on the left labeled 'Date of birth' pointing downwards. Herd A contains 7 cows, and Herd B contains 8 cows. The cows are represented by simple line drawings. The text 'Properties of BLUP EBVs' is located at the bottom right of the diagram area.

Possible causes of bias 'fixed effects'

Can account for some bias easily e.g.

- ❖ Problem: Some animals reared as singles, other as twins
- ❖ Solution: Correct phenotypes for effect of rearing type

- ❖ Problem: Animals producing in different herds
- ❖ Solution: Take phenotypic deviation from herd mean

- ❖ Problem: Animals are measured at different ages
- ❖ Solution: Correct phenotypic observations for age

Properties of BLUP EBVs

Possible causes of bias 'fixed effect confounded with genetic effect'

- ❖ Problem: Animals producing in different herds, and the different herds have different genetic means (*no longer can take phenotypic deviation from herd mean*)
- ❖ Solution: Use reference sires as links between herds, and simultaneously evaluate herd and sire effects

A feature of BLUP

Properties of BLUP EBVs

Use of link sires

Progeny means

Flock	Sire 1	Sire 2	Sire 3	Sire 4	Sire 5
A	45	40			45
B			45	40	50

Sire 1 is superior in flock A, & sire 3 is superior in flock B.

But which sire is the best overall?

Properties of BLUP EBVs

Use of link sires

Progeny means

Flock	Sire 1	Sire 2	Sire 3	Sire 4	Sire 5
A	45	40			45
B			45	40	50

Assuming ewes are of equal merit in flock A and flock B, the sire 5 data indicates that flock B is performing in a better environment.

Thus sire 1 is genetically superior to sire 3, as sire 1 produces the same phenotype despite the worse environment.

Properties of BLUP EBVs

In practice

- ❖ Linkage between herds / flocks within the major genetic evaluation systems (e.g. LAMBPLAN / BREEDPLAN) is now substantial
- ❖ This allows across-flock and even across-breed analysis

Properties of BLUP EBVs

Possible causes of bias 'unequal merit of mates'

❖ Problem: Some sires have better mates

Sire 1: +300	Dam 1: +200	Progeny: +250
Sire 2: +300	Dam 2: +400	Progeny: +350

Without information on the dams, sire 2 would 'look better' due to a higher progeny mean

❖ Solution: Account for mates by evaluating all animals jointly

A feature of BLUP

Properties of BLUP EBVs

In practice

- ❖ Genetic evaluation systems encourage recording of phenotypes on mates
- ❖ If no dam information is provided, the dam is presumed to be 'average'

Properties of BLUP EBVs

Possible causes of bias 'selection bias'

- ❖ Problem: There is culling and selection
 - worst sires have more progeny culled 'culling bias'
 - animals are from selected parents

Properties of BLUP EBVs

Culling bias

<i>ID</i>	<i>Sire</i>	<i>Weaning Weight</i>	<i>Progeny mean</i>	<i>Yearling Weight</i>	<i>Progeny mean</i>
101	1	160		300	
102	1	140	140	280	280
103	1	120		260	
104	2	140		280	
105	2	120	120	260	270
106	2	100		no record as culled	

Sire 2 gets an unfair 'lift' in progeny mean of yearling weight, due to culling at weaning.

Properties of BLUP EBVs

In practice

- ❖ Information on culled animals should be included in the evaluation
- ❖ Similar to links between herds, links between years are required

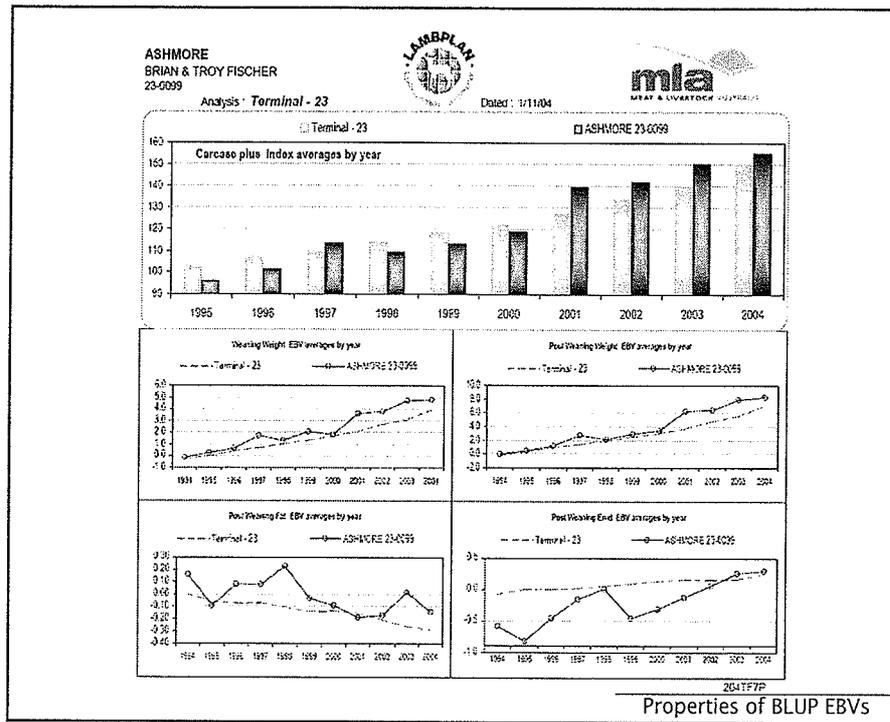

Properties of BLUP EBVs

Genetic trends

As BLUP separates genetic and year effects

genetic trends can be observed by plotting
BLUP EBVs over years

Properties of BLUP EBVs

In practice

- ❖ Genetic evaluation services often provide genetic trends to their clients
- ❖ Genetic trends are used as marketing tools

Possible causes of bias 'unbalanced designs'

- ❖ Problem: Some animals have more information than others
 - different number of sibs
 - different number of progeny
 - etc.
- ❖ Solution: Construct a 'customised' selection index for each animal

A feature of BLUP

Properties of BLUP EBVs

In practice

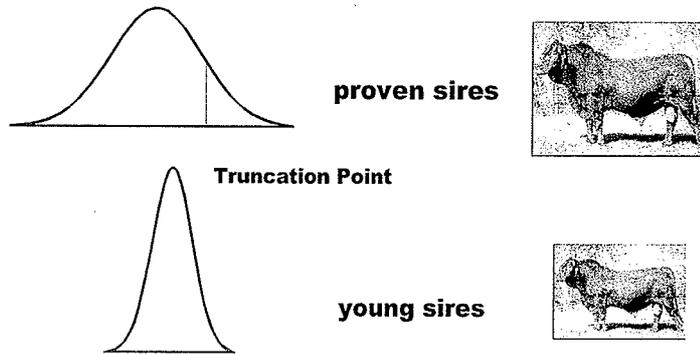

- ❖ Optimal weightings are placed on each information source
- ❖ Only the EBVs (rather than the index weights) are reported

Properties of BLUP EBVs

Another feature of BLUP

EBVs can be compared directly over age classes

Selection on BLUP EBVs results in optimisation of the generation interval

Another feature of BLUP

BLUP uses family information (and more so at lower heritabilities)

Selection on BLUP EBVs can thus result in higher F than selection on phenotypes alone

Properties of BLUP EBVs

How BLUP works

A joint evaluation of all animals

- ❖ uses all additive genetic relationships
- ❖ uses data on all animals jointly

Works as a linear model

- ❖ corrects different effects for each other
- ❖ jointly estimates animal effects and fixed effects

Has selection index properties

- ❖ each EBV is the result of a customized index

Properties of BLUP EBVs

BLUP summary

Optimal weights for all information sources

- ❖ *lots of different sets exist of optimal weighting factors, BLUP does it automatically*

Allows comparisons of EBV's of animals in different herd (possibly with different genetic means)

- ❖ *but links need to exist in the data!*

Accounts for culling and selection, non-random mating

- ❖ *but culled, non selected animals and mates need to be included in the analysis!*

Allows selection across age classes – optimises generation interval

Provides an estimate of genetic trend

Properties of BLUP EBVs

In practice

Accuracy of BLUP EBVs depends on quality of the data (as well as the trait heritability)

- ❖ Accurate phenotypic measurements
- ❖ Correct pedigree
- ❖ Correct recording of fixed effects & assignment to contemporary groups
- ❖ Appropriate data structure (e.g. information on mates, culls)

Remember, if BLUP doesn't know a piece of information, it cannot account for it

Properties of BLUP EBVs

Questions

How easy would it be to cheat the system ?

Could an animal have different EBVs when evaluated under more than one evaluation systems ?

When is an animal's EBV likely to change within the one evaluation system ?

Properties of BLUP EBVs

From a 'letter to the editor' submitted to *The Land* 1999. Indicates a lack of understanding by the breeder.

"Dr Banks criticises [a particular genetic evaluation system] as he believes it is only regarding phenotype — the individual animal — while Lambplan can compare animals across flocks, regions, climates and feed buckets ...

However, as a current user of Lambplan, we can say the question of feed history of our sheep is never asked for, nor recorded so environmental factors have no say."

Properties of BLUP EBVs
